This version: July 2009

We study the market for CEO talent in public U.S. firms during the years 1993-2005. CEO talent pools are not homogenous across firms and industries. About 68% of new CEOs are former employees of their own firms ("insider CEOs") and the rest come from outside the firm ("outsider CEOs"). We find wide disparities in talent pool structure across industries, with some industries having almost no outsider CEOs and other industries having a majority of outsider CEOs. Our central conjecture in this study is that, to the extent that the exogenous (to the firm) costs of hiring CEOs from outside the firm limit the potential outside options of the CEO and the firm, the compensation to the CEO should depend more on the compensation distribution within the pool rather than outside the pool. Consistent with this conjecture, industry talent pool structure helps explain several compensation practices: CEO compensation is benchmarked against other firms only in industries that have high percentage of outsider CEOs and pay-for-luck is less prevalent when the industry has a low percentage of outsider CEOs. Finally, while CEO talent pools seem to explain cross-sectional variations in CEO compensation, they have little power in explaining the rise in CEO compensation in public U.S. firms in recent years.

[*] We thank Viral Acharya, Jonathan Cohn, David DeAngelis, Xavier Gabaix, Eric Talley, and participants at the Conference for Empirical Legal Studies at Cornell (2008), NBER Corporate Finance (2008), Western Finance Association (2009), Simon Fraser University, Northwestern University, SUNY Binghamton, Tel Aviv University, IDC, the University of Colorado at Boulder, and the European University Institute in Florence (Italy) for valuable feedback. 1. Introduction

Over the last several decades scholars have taken different views on the role of the market for CEO talent in shaping executive compensation. Many theorists view the market for CEO talent as quite competitive and homogenous across firms and industries (e.g., Rosen, 1992, Gabaix and Landier 2008, Himmelberg and Hubbard 2000, Hubbard 2005). Other scholars argue that CEO talent is not always easy to substitute, because e.g. managers need to have firm- or industry-specific knowledge (e.g., Jovanovic 1979, Becker 1979), or because they have unique styles (Bertrand and Schoar 2003), or because of the time required to learn whether the manager is a good match to the firm (Jovanovic 1979), or because managers may entrench themselves (Jensen 1986, 1993, Shleifer and Vishny 1989, Bebchuk 2006).

The level of heterogeneity of managerial talent pools has far-reaching implications for executive compensation (see in particular Murphy and Zabojnik 2004, 2007). To the extent that the market for corporate talent is homogenous and competitive, CEOs and firms match such that CEO compensation would in equilibrium reflect the demand and supply for their services (Gabaix and Landier 2008). However, if talent is largely firm-specific and difficult to substitute, then both managers and firms would have very few outside opportunities, and compensation would be shaped by the bargaining position that each party has in the negotiation process (Jensen 1993, Bebchuk and Fried 2003).[2] Following this, our central conjecture in this study is that, to the extent that the exogenous (to the firm) costs of hiring CEOs from outside the firm limit the potential outside options of the CEO and the firm, the compensation to the CEO should thus depend more on the compensation distribution within the pool rather than outside the pool.

In this study, we shed light on the level of heterogeneity in managerial talent pools and the relation between CEO talent pool structure and executive compensation.

[2] The labor literature has studied segmentation in certain labor markets beyond the market for managers. See, for example, Dickens and Lang (1992) for a review of the literature and Reich, Gordon, and Edwards (1973) and Dickens and Lang (1985) for theoretical work. For more recent empirical studies see, e.g., Lazaer and Oyer (2004).

Our first step is to identify the pools for CEO talent across different industries. Toward that end, we collect information from 1,827 CEO replacements in S&P 1500 companies between the years 1993 and 2005. For each new CEO, we identify her position before becoming CEO, as well as the firm and the industry from which she arrived. From these revealed choices of firms and new managers, we draw inferences regarding the talent pools from which CEOs in different companies and industries are chosen.

We find that, in general, managerial talent pools are quite industry-specific and often even firm-specific. Prior experience in managing production is one of the fundamental skills that new CEOs often have. Using the Fama-French 10 industry groups and excluding interim CEOs (about 7% of new CEOs), 86% of the new CEOs come from the same industry sector, split between lower-level managers of the same company *(68%)* and managers from other companies within that same industry *(18%)*. We find little variation over time. For example, 86% of the new managers come from the same industry in 1993-1995 compared to 87% in 2003-2005. Moreover, we find wide disparities in the percentage of insider CEOs across industries.

Firms are more likely to choose CEOs from inside the firm or from inside the industry when the industry faces more investment opportunities, and when there are more investments in R&D at the industry level. These findings are consistent with the idea that past experience in the firm or in the industry is more advantageous when specific knowledge associated with research and development or with investments seem more important to the firm.

Next, we study the relation between talent pool structure and executive compensation. First, we explore whether talent pool structure is related to compensation structure. We find that industries in which firms choose CEOs from outside the firm rely more on equity-based compensation than industries in which firms choose CEOs from inside. Thus, greater equity-based compensation may be required to attract and sustain talent when CEOs have more opportunities outside the firm.

Second, we study the relation between CEO talent pools and the practice of benchmarking compensation. A common practice by many boards of directors is to use peer firm groups from the same industry and with similar size to benchmark CEO compensation. Past studies have noted that this widespread practice is a way to ensure that CEOs are paid a competitive salary that is commensurate with their outside options (Bizjak, Lemmon, and Naveen 2008).

We postulate that talent pool structure could have a significant impact on the practice of benchmarking. If benchmarking is used to compensate the manager for outside opportunities, then it should be more prevalent in industries in which talent is not firm-specific, since in those cases, compensation in other firms better reflects the outside opportunities of firms and managers (Holmstrom and Kaplan 2003). However, in industries in which talent is firm-specific, benchmarking should be less prevalent since the CEO does not have a viable option to work as a CEO in another company in.

Consistent with the above conjecture, we find strong evidence that benchmarking is prevalent *primarily* in industries in which new CEOs tend to come from outside the firm. In contrast, the compensation to the CEO is not affected by changes in the compensation of CEOs in peer firms in industries in which CEO talent pools are almost entirely firm-specific.

Third, we study the relevance of industry-wide shocks to CEO compensation. Previous studies have shown that firms tend to tie CEO compensation not only to firm-specific performance but also to performance of the industry and the market as a whole (e.g., Bertrand and Mullainathan 2001, Aggarwal and Samwick 1999). This “pay-for-luck” was interpreted as a bad compensation practice by some scholars (e.g., Bertrand and Mullainathan 2001, Bebchuk and Fried 2003), while others have raised the possibility that this correlation is due to a correlation between industry conditions and supply and demand for CEO talent (Himmelberg and Hubbard 2000, 2005). We find evidence of a stronger relation between compensation and industry performance in industries that have the largest percentage of outsider CEOs. In contrast, the relation between firm performance and

industry performance is weaker in industries where talent pools are more firm specific. This result seems consistent with CEO labor market competition (partly) driving the relation between CEO compensation and industry-wide performance.

Fourth, we study the extent to which variations in talent pool structure across industries explains time-series variations in CEO compensation. Many studies have emphasized the importance of return-to-talent and variation in return-to-talent in explaining the level and changes in the level of executive compensation in recent years. Gabaix and Landier (2008, henceforth GL) present a model in which more talented CEOs are attracted to larger firms, predicting that changes in CEO compensation should depend both on changes in the size of the firm in which the CEO operates and the changes in the size distribution of firms in the economy (capturing the productivity of talent across firms, and hence the outside opportunities of CEOs with different talents). Their specification assumes that CEO skills are substitutable across firms, and that profitability is a function of skills and firm size. Therefore, in equilibrium, more talented CEOs will be attracted to larger firms. Given our findings of the importance of heterogeneous firm- and industry-specific skills, we explore whether the size distribution of firms in the industry (arguably the more relevant measure of productivity of talent in actual CEO talent pools), better explains variation in compensation than size distribution of all firms in the economy.

We find that despite the evidence of fragmented CEO talent pools, variations in firm size (as a proxy for talent as in GL) within industries explain only a very small portion of the variation in CEO compensation over time. We find this result puzzling and explore several reasons for this finding. One possibility is that executive talent may make career decisions early on, knowing that once they enter an industry they cannot leave. However, in that case more talented potential CEOs may enter industries with higher rewards, restoring equilibrium compensation that is again driven by market-wide, not industry-specific factors.[4] Empirically though, we find that insider CEOs typically

[4] We thank Xavier Gabaix for proposing and illustrating this possibility in his NBER discussion of our paper.

have very long tenures with their own firm before becoming CEOs. For example, more than 90% of new insider CEOs have been with their firms 5 years or more, and thus would likely have made their career decisions many years before that. As a result, projections regarding the potential growth of different industries would arguably seem to be hard to make that far in advance by young executive talent deciding on their career path.

Second, the size of the market-wide reference firm may proxy for something else not directly related to the equilibrium model in GL. Recent papers challenging the interpretation of GL include Frydman and Saks (2007), who find a much smaller elasticity between CEO compensation and average firm size with data starting in 1936, as well as Dew-Becker and Gordon (2007), who find widely varying elasticities for 1970-2005 compensation data using rolling 20-year regressions.

The rest of the paper continues as follows. In section 2, we describe our data collection process and the construction of the main variables, explain talent pool structure differences across industries, and, finally, explore how CEO talent pool structure is related to the level, growth and the equity-based incentives in CEO compensation. Section 3 provides the analysis of the benchmarking results and section 4 of pay-for–luck. In section 5, we revisit the Gabaix and Landier (2008) framework and section 6 concludes.

2. Data and variables

We study the market for CEO talent by identifying the background of new CEOs in the largest public U.S. corporations. Our universe of firms includes all firms in the Execucomp database for the years 1993-2005. Execucomp provides information on the five highest paid top executives for firms included in the S&P 1500 composite index (or that have belonged to it in the past). Our sample starts in 1993, as Execucomp started a full collection of the data then. The database consists of 24,084 firm-year observations.

2.1 Identifying new CEOs

We first identify entry of new CEOs in the sample. Table 1 shows the identification procedure. For some firms in the database, Execucomp identifies the executive who is the CEO (variable *annceo*), and the year in which the CEO was appointed or reappointed (variables *becamece* and *rejoin*, respectively). For firms for which these three variables are available, we define a 'new CEO' as a CEO whose year of becoming a CEO or of rejoining the firm is the same as the recorded firm-year. This procedure allows us to identify whether a CEO is new in a total of 21,339 firm years.

For firms with missing data on *becamece* and *rejoin* but where *annceo* is not missing, we look at whether the same executive was identified by Execucomp as a CEO in the previous year. If a different executive was the CEO then we define the current CEO as a new CEO. If the variable *annceo* is also missing or if the firm is not in the database in the previous year, then we read the proxy statement in that year and in the previous year to identify whether the CEO is new. This procedure allows us to identify whether the CEO is a new CEO in additional 2,064 firm-years. Our final sample therefore consists of 23,403 firm-years or 97% of the entire Execucomp database. Of the 23,403 firm years we identify 1,890 firm years in which the CEO was new.[5]

2.2 Identifying CEO Background

Securities regulation section 229.401 requires that firms provide background information in their proxy filings about each executive officer and director. This information includes each person's principal occupations and employment during the past five years; the name and principal business of any corporation or other organization in which such occupations and employment were carried out; and whether such corporation or organization is a parent, subsidiary or other affiliate of the firm.

[5] For 3% of firm-years, we could not identify whether the CEO was a new CEO in the particular year for various reasons, such as the firm does not identify who the CEO is, or the firm has more than one CEO or the firm does not have electronic filings in that particular year to ensure that the CEO is new.

We read the background information for each new CEO from the proxy statements and identify the name of the previous employer of the CEO and the occupation of the CEO under that employer. We were able to find proxy statement information for 1,827 out of the 1,890 new CEOs (about 97%).

In some cases, new CEOs are entering the firm few months before becoming CEOs, to ensure a smooth transition with the current CEO. We argue that the last employer of these new CEOs (i.e., before becoming CEO) should not be the current firm, since the decision to have them as CEOs was most probably made before they entered the current firm. Instead, if the CEO was affiliated with the current firm for less than two years, we use the previous employer and position of the CEO as the new CEO's last position before becoming CEO. In other cases, boards choose interim CEOs while looking for a new, non-interim CEO. We define a CEO as an interim CEO if the firm explicitly writes in the proxy statement that the CEO is an interim CEO, or if the CEO is replaced within a year of becoming a CEO.

Next, we identify the four-digit SIC industry code of the new CEOs' previous employer. If the previous employer is a public firm, the industry code is taken from the CRSP header file. If the employer is a private firm, the code is taken from the Hoovers' database. In the few cases where the information is not available in CRSP or in the Hoover database, we assign an industry code based on the SIC code description and the information that we collect about the previous employer.

Table 2 presents summary statistics of our sample. Panel A shows that out of the 1,827 new CEOs between 1993 - 2005, 1,147 (63%) are insiders, whose prior employer was the firm for at least 2 years.[6] An additional 547 new CEOs (30%) are outsiders, i.e. they did not work for at least 2 years in the firm before becoming CEOs. An additional 133 new CEOs are interim CEOs (7%). From the 547 outsiders in the sample, a total of 312 CEOs come from a firm that belongs to the same industry

[6] SEC regulations require directors to provide information about prior occupations in the past five years. We can therefore fully track the occupations of new CEOs up to five years before becoming CEOs. We find that about 93% of the new insider CEOs worked in their firms for at least 5 years before becoming CEOs.

(not shown).[7] Therefore, a total of 1,459 CEOs come from either inside the firm or from a firm in the same industry, which is 86% of all non-interim CEOs.

Panel A also shows that these characteristics are relatively stable over the years. Between 1993 - 1996, 63% of the new CEOs were insiders, 31% were outsiders, and 57% of the outsiders came from within the industry, compared with 60%, 32%, and 59% in the years 2003 - 2005.[8]

These numbers are consistent with the numbers in Murphy and Zabojnik (2007), who find an average of 32.7% of new hires between 2000 - 2005 are outside hires. For the years 1990 - 2000 they find an average of 27% of CEOs who are outside hires, but their sample for that period includes only Forbes 500 firms, which are larger firms than the firms in our study and larger firms tend to hire fewer outsider CEOs.

Table 2 panel B shows the distribution of prior occupation of outsider CEOs. Out of the 547 outsider CEOs, 32% were already CEOs in other companies before joining the firm, out of which 19% were CEOs in public companies. However, the majority of new outsider CEOs (68%) were not CEOs in their previous employment, although many of them came from public corporations (48%).

Prior occupations of outside CEOs have changed somewhat over the years. There are slightly more former CEOs in recent years than in previous years (36% in 2003-2005 vs. 30% in 1993-1995). This increase seems driven by an increase in hires of former CEOs from the private sector (18% in 2003-2005 versus 13% in 1993-2005).

Table 2 panel C shows additional information on the background of outsider CEOs with no prior CEO experience. We show the most frequent prior occupations for 340 of the 374 new CEOs. The panel shows that the most frequent prior occupation is management of a division or a subsidiary, or being a vice president (43%), followed by chief operating officer and president (8% and 11% respectively).

[7] Our industry definitions follow those on Kenneth French's website, using the 10 industry group classification here (in the later sections we primarily use the 48 industry groups). Using 48 industry groups, the number of managers who come from the same industry is 215.

[8] Other studies point to an increase in outside hire over time, occurring in an earlier period (e.g. Frydman 2005).

Table 2 panel D shows the distribution of prior occupation of insider CEOs. The table is based on the subsample of 599 insider CEOs for whom we collect this information from proxy filings. The most common prior occupation of the insider CEOs is Chief Operating Officer (39%), followed by division manager / Vice president (23%) and company President (20%). These three positions are mainly operational, and involve managing the day-to-day operations of the company. Only 4% of the insiders' previous job is Chief Financial Officers, suggesting that specialized skills in the financial aspects of the firm are not that important for new CEOs.

Finally, there hasn't been much change in prior occupation of new insider CEOs over the years, though there seems to be a decrease in the frequency of COOs as prior occupation and an increase in the frequency of division managers as prior occupations until 2000. This is consistent with Rajan and Wulf (2006) who find a decrease in the COO positions and flattening of managerial hierarchies during that time. The effect, however, reverses from 2000 onwards.

2.3 CEOs and Industry pools

Since CEOs are coming mostly from within the corporation and outsider CEOs are typically from the same industry group, experience in the firm and its industry seems to be a significant determinant of CEO hiring. In this subsection, we take a closer look at the industry experience of new CEOs. We count the number of new CEOs from each of the 10 industry groups from which they come from, and measure what fraction of these accepted a CEO position in each of the 10 industry groups. This results in a 10 by 10 matrix, where each row represents an industry from which CEOs come and each column represents an industry to which CEOs go. In each cell (i,j) we calculate the fraction of CEOs coming from industry i and going to work in industry j, using the whole sample.

Table 3 panel A shows the 10 by 10 matrix. Also included in the panel is the number of insider and outsider CEOs for each of the 10 industry groups (first 2 columns). The panel shows that there is a large variation in the percentage of insiders across industries. The industry with the fewest insider CEOs is the high-tech industry, where only 55% of the new CEOs are insiders. The industry with the largest number of insider CEOs is the energy sector, where 83% of the CEOs are firm insiders.

The next 10 columns show the migrations of outsider CEOs across different industry groups. For example, the first row shows that out of the 28 new CEOs in the industry which produces nondurable goods, 18 (64%) came from that same industry, 3 (11%) came from the manufacturing industry, one (4%) came from the wholesale and retail industry and 6 (21%) came from the 'Other' industry.

Likewise, there is a large variation across industries in the talent pools from which companies choose new CEOs. For example, firms in the high-tech industry choose new CEOs from almost all industries. In contrast, firms in the health sector choose CEOs from only 4 industry groups.

The table also summarizes the portion of new CEOs coming from a certain industry group ending up in another group. For example, column 1 shows that out of the 37 candidates who had experience in the nondurable good industry, 18 (47%) became new CEOs in the nondurable good industry, one (3%) became a CEO in the durable good industry, 7 (19%) became CEOs in the manufacturing industry, 6 (16%) became CEOs in the high-tech industry, etc. To illustrate the large variation in the distributions, CEOs in the manufacturing industry come from 9 different industries whereas CEOs in the energy industry come from only two industries.

Our classification of industries might be too coarse, and therefore might miss some variations in outsider CEO hires within classified industry groups. We therefore also consider in panel B of Table 3 the distribution of outsider and insider new CEOs across a finer classification of 48 industry

groups. Among industries that have 10 or more replacements in the database, the industries that have the largest percentage of insiders are Construction (92%), Steel Works (85%), and Transportation (82%). Among the industries that have the smallest percentage of insiders are Trading (41%), Aircraft (47%), Computers (51%) and Personal Services (53%).

2.4 Explaining Industry CEO Talent Pool Structure

Table 3 shows that, for the most part, CEOs are coming from either their own firm or from within the same industry. However, there is also large variation in talent pool structure across industries. In this section we try to get a better idea of the possible reasons for the differences in CEO talent pools.

Searching for new CEOs is inevitably a costly task. In their search, directors presumably weigh the cost of looking for the best candidate against the benefit for hiring that candidate. It seems natural to expect hires from within the organization to be associated with fewer risks since such candidates have already proven to be a good match with the firm, are already familiar with the firm, and the firm has fewer uncertainties about their qualifications. Firms which choose outside candidates would presumably face larger search costs due to uncertainties about the match with the firm of an outside hire, uncertainties about the true qualifications of an outside hire, etc. These costs could be the most important driver for hiring a CEO candidate from inside the organization. On the other hand, the drawback of hiring an insider is that the pool of candidates within the organization is limited. Thus, the firm might forgo better candidates from outside the organization by limiting itself to internal hires.

This cost-benefit tradeoff implies that internal hires, external hires from within the industry, and external hires from outside the industry, will be determined by the tradeoff between the cost and benefits of hiring from inside and outside. When the costs of hiring from outside are high and the benefits are low, firms will be more likely to choose candidates from within the organization. If the

costs of hiring from outside are low and the benefits are high, firms will choose candidates from other organizations and even from outside the industry.

In order to explore empirically explanations for the variation in the level of outside CEOs across industries, we consider various proxies for possible frictions in the CEO labor market.[10] First, a talent pool may be firm-specific or industry-specific if there are firm-specific skills that the manager needs to acquire in the organization that he or she cannot acquire in other firms or in other industries. We conjecture that high level of research and development in the industry and high level of capital expenditure in the industry will be related to fewer hires from outside the industry and more hires from within the firm. Our proxy for research and development at the industry level is the median R&D to Sales ratio across all firms in Compustat that belong to the industry, and our proxy for capital expenditure is the ratio of Capital Expenditure to Sales across all Compustat firms in the industry.

Second, larger number of employees within the firm will provide a large pool of candidates to choose from and therefore a firm will be more likely to choose candidates from within the organization if it has larger number of employees. We expect larger percentage of hires from within the organization if there are more employees per firm within the industry. Our proxy for the number of employees in the industry is the median log of the number of employees across all Compustat firms that belong to the same industry.

Third, industry structure could also affect the choice of the firm whether to hire from outside or from inside the firm or the industry. To the extent that the industry is more concentrated, there might be fewer opportunities to hire managers from outside the firm. Firm-specific strategies might be more important also in concentrated industries and therefore CEOs from outside the firm might not have the right skills to run the firm. We introduce the Herfindahl index as a measure of the level

[10] Agrawal, Knoeber and Tsoulouhaus (2006), and Tsoulouhaus, Knoeber, and Agrawal (2007), also explore the choice of firms between insider and outsider CEOs. Their focus, however, is on the hypothesis that the firm commits not to choose outsider CEOs in order to increase incentives of lower-level managers ex-ante. In contrast, we focus on exogenous, industry-level frictions outside board control, which affects the costs of searching for outside CEOs.

of industry concentration. We measure industry concentration across all firms in Compustat that belong to the same industry.

Fourth, industries could face large shocks of strategic and technological changes.[11] In these cases, the old strategy of the firm might not work well or might not be relevant anymore and the firm is required to change its strategy. In such a case, the added value of hiring a candidate from inside the firm will be low, since familiarity with existing practices within the firm might not be relevant. Moreover, talent might have a larger effect on firm value when firms are going through changes and therefore looking at a large pool of candidates from other firms might have a larger added value. We thus expect industries that go through large changes to be associated with more hires from outside the organization. Our proxy for industries that go through large changes is the percentage of replacements out of the total number of firms in that industry. This variable captures the need for change in personnel in the industry.

Industries could also attract new talent if the industry is growing. We capture the growth in the industry by the increase in log sales across all firms in Compustat in a given year from the previous year.

Fifth and finally, for a given cost of search, the larger the return to talent the more likely the firm is to expand its pool of potential candidates. Our proxy for the return to talent is the industry-level profitability and the industry-level Tobin's Q.[12]

Table 4 shows the regression results for the determinants of industry-level talent pools. In columns 1-2 the dependent variable is the percentage of new hires from inside the firm across the Fama-French 48 industries. In columns 3-4 the dependent variable is the percentage of new hires

[11] For analysis of the dynamics of outside CEO options, see for example Eisfeld and Kuhnen (2009).

[12] We also explored the effect of variability of profitability across firms within the industry on the likelihood that the industry will rely on outsider CEOs. The argument being that firms are more likely to choose outside CEOs if the variability of talent across CEOs is higher, (suggesting that there are higher rewards to searching for CEOs outside the firm). We use the difference between the ninetieth percentile and the tenth percentile of ROA distribution at the industry level to measure of performance variability. The variable is not statistically significant.

from outside the industry across the Fama-French 48 industries. We use two data specifications. In the first specification we use year dummies and in the second specification we omit them.

The results across the two data specifications are quite similar. The main variables related to a larger percentage of insider CEO hires from within the firm are high capital expenditure and, more generally, larger growth in the industry. Hires from outside the industry are less likely when the industry has more R&D and more capital expenditure, suggesting that familiarity with the firm-specific and industry-specific technology might be important for CEO hires. In addition, there is some evidence that firms are also more likely to hire CEOs from outside the industry if there are fewer firms in the industry and when replacements in the industry are more frequent.

Overall, our results are consistent with the idea that talent pools, or the percentages of outside CEOs in an industry, are related to a cost-benefit analysis as discussed above, and are partly driven by the complexity of the firm that CEOs manage.

2.5 CEO Talent Pool Structure: level, growth and composition of CEO Compensation

Our central conjecture in this study is that, to the extent that the exogenous (to the firm) costs of hiring CEOs from outside the firm limit the potential outside options of the CEO and the firm, the compensation to the CEO should depend more on the compensation distribution within the pool rather than outside the pool. Before getting to the main analysis, in this subsection we first explore whether CEO talent pool structure itself has any association with the level, growth and composition of CEO compensation.

With respect to the composition of CEO pay, we focus on the difference between the level of equity-based incentives across talent pools. Equity-based compensation has been considered in the literature as a way to sustain and retain executive talent (e.g. Oyer 2004), and so stronger competition for CEO talent should be associated with more equity-based compensation.

To capture the level and growth of CEO compensation, we use the log CEO of total compensation (Execucomp variable TDC1) and the changes in the log of CEO total compensation, respectively. We consider two proxies that capture the importance of equity-based incentives within the composition of CEO pay. The first is the ratio of the dollar value of restricted stock grants and option grants over total compensation (TDC1). This measure captures the flow of equity-incentives to the CEO. The second is the sum of the reported value of restricted stock holdings and option holdings (exercisable and unexercisable) as of the end of the fiscal year, as a proxy for the stock of equity incentives. Our independent variables are three different proxies related to CEO talent pools: (i) a dummy for whether or not the CEO comes from the outside, (ii) the percentage of CEOs in the industry that comes from the inside, and (iii) the percentage of outside CEOs in the industry that comes from the same industry.

Finally, we also add a proxy for the general level of outside opportunities for all top executives (including the CEO) in other industries. This last proxy is the ratio of the number of top executives in the industry that became CEOs outside their industry, divided by the number of firms in the industry. We obtain the number of the top executives in the industry that became CEOs outside their industry from our database by counting the number of CEOs outside a given industry who came from that given industry. This variable captures the level of outside opportunities to non-CEOs within a given industry. This proxy is added because our existing measures of the CEO talent pool (in particular the number of outside CEOS in the industry) might not fully capture outside opportunities to lower-level managers outside the industry, which we also want to control for.

We further add a set of controls that has become standard in the executive compensation literature, including lagged total CEO compensation, the Herfindahl concentration index based on sales using all firms in Compustat in the industry, stock price volatility, market beta, performance (return on equity, equity market capitalization and its one-year lag and growth in log sales), the market capitalization of the 250th largest firm in the current and the previous year (see GL) and CEO

tenure. Descriptive statistics for the four CEO talent pool proxies and all controls can be found in Table 5, and the regression results are presented in Table 6, in which the robust standard errors are clustered by firm.

For the association between CEO talent pool structure and the level of total compensation accruing to the CEO, there are two main competing hypotheses. Murphy and Zabojnik (2007) argue that outsider CEOs have more generic management skill that are relatively rare, such that outsider CEOs command higher level and growth in their salaries. Industries with more outsider CEOs could be industries where the need for such relatively rare, generic skills is greater. On the other hand, Bebchuk, Fried, and Walker (2002) and Bebchuk and Fried (2003) suggest that high (growth in) levels of CEO pay tend to results from captive boards. As outsider CEOs seem less well-positioned to influence boards, especially in the beginning of their tenures, this hypothesis would imply that outsider CEOs have lower levels and growth of pay.

Likewise, the association between equity-incentives and CEO talent pool structure has two alternative hypotheses. On the one hand, in industries with few outsider CEOs, CEOs may need additional incentives to compensate for the lack of incentives presented by outside opportunities. On the other hand, greater outside opportunities may need to increased need to bind the CEO to the firm, e.g. through greater incentives. Further, the more competitive environment of more outside hires may also lead to greater board diligence. Similarly, Huson, Parrino, and Starks (2001) and Hermalin (2005) suggest it reflects increased board monitoring. Such board may also opt for a more significant link between pay and performance, through increased equity-based pay.

The results of Table 6 indicate that outside CEOs receive more compensation, both in level (about 8.7% higher), confirming the results in Murphy and Zabojnik (2007). There is marginally significant evidence that firms in industries with more outside CEOs pay more to their CEOs. However, outside CEO salaries do not seem to grow faster than other CEOs, while we find some evidence that CEO pay in industries with more outside CEOs grows faster. A one standard deviation

increase in the percentage of outside CEOs in the industry (10%) is associated with an increased growth rate of about 2% a year (= 0.202 x 10%).

Finally, we find that CEOs receive more equity-based compensation and have higher equity-based holdings in industries with more outside CEOs. However, the economic magnitudes are relatively small. For example, a one standard deviation increase in the percentage of outside CEOs is associated with an increase in the percentage of equity-based pay of about 2% a year (= 0.198 x 10%). This finding suggests that industries with high competition for CEO talent rely more on equity-based compensation to perhaps retain managerial talent, which seems consistent with Oyer (2004).

3. Benchmarking

Our goal is to study the extent to which variations in talent pools explain cross-sectional variation in CEO compensation. We conduct three tests of the effects of the talent pool structure on the structure of CEO compensation. The first test measures the extent of benchmarking CEO compensation (this section), the second explores the importance of 'pay-for-luck' or pay for industry-wide performance (section 4), and the last considers the relation between firm size and compensation as in GL (section 5).

In determining CEO compensation, public corporations as well as compensation advisors rely on compensation to CEOs in other, similar firms. This practice, called benchmarking, is perhaps the most convenient way to ensure that CEO compensation is adjusted for changes in the supply and demand forces in the economy for CEO talent and to establish a CEO's reservation wage (Holmstrom and Kaplan 2003). On the other hand, benchmarking opponents have been worried that benchmarking may lead to CEO compensation increases regardless of performance.

Bizjak, Lemmon, and Naveen (2008, henceforth BLN) find widespread evidence of benchmarking CEO compensation to that of other firms, but no systematic evidence that the use of

benchmarking is more prevalent in firms with weaker governance. They also find that benchmarking is more likely for executives with shorter tenure and with better firm performance. BLN also consider labor market effects through proxies such as firm age and the unemployment rate, but do not consider direct evidence from CEO talent pools as this paper.

CEO talent pools could have a significant effect on benchmarking. In industries with a large fraction of outsider CEOs, the CEO's outside option should be determined by the compensation of CEOs in other firms, most likely in the same industry. In a competitive labor market, firms would adjust the compensation of the CEO to that of others in the industry (Oyer 2004). If, however, there are very few outsider CEOs in the industry and the relevant talent pool of CEO candidates is given by top executives from inside the firm, then CEO compensation in other firms should not be an important determinant of the compensation to the manager. In those industries, any evidence for benchmarking could rather be interpreted as evidence for opportunistic pay-setting practices, or CEOs being compensated without regard to changes in their outside opportunities.

3.1 Benchmarking Methodology

A natural way to examine whether CEO compensation is benchmarked against peer groups is to test whether changes in CEO compensation between year t-1 and year t are explained by the relative position of the CEO compensation in year t-1 vis-à-vis compensation in the peer group (the benchmark), after controlling for the relevant variables that determine compensation. In particular, we closely follow the procedure in BLN, whose specification is as follows:

$$\Delta Compensation_{i,t} = a_1 * Distance(Compensation_{i,t-1}, Benchmark\ Compensation_{t-1}) + a_2 * Controls_{it} + Error_{it}. \quad (1)$$

The function *Distance(Compensation*$_{i,t-1}$*, Benchmark Compensation*$_{t-1}$*)* is a measure of the distance between CEO compensation in year t-1 and the benchmark compensation in the same year. Like BLN, we consider the benchmark compensation as the median compensation in the peer group in the previous year and employ two different proxies for such distance. First, a Low Compensation Dummy that equals one if compensation$_{i,t-1}$ < benchmark median compensation$_{t-1}$, and zero otherwise. Second, the cumulative distribution function of the difference between the last year's benchmark median compensation minus the firm's compensation last year (CDF Distance). CDF Distance is positive if last year's CEO pay was below the peer group median and is negative when last year's pay was above the peer group median.

The benchmark group formation also closely follows BLN, and is based on industry and size. Each year and within each of the 48 industry groups, we classify firms as being in one of two industry size groups: namely the large (small) firm group if they have market capitalization above (below) the industry median. Each firm's benchmark group is then given by all firms in the same industry-size group, such that with 48 industry groups, there are 96 industry-size groups.

The control variables include performance measures (return on equity in the previous year, change in log shareholder value from previous year and growth in log sales) as well as CEO tenure. As GL suggests that changes in the distribution of firm size across large firms in the economy affect CEO compensation, we also include as control variables the market capitalization of the 250th largest firm in the current and the previous year. We further add the Herfindahl concentration index based on sales to control for the product market structure.[13] Finally, we add the firm's stock price volatility and its market beta (both based on the last 5 years) to control for differences in risk, which may be particularly important for the valuation of the option packages (see also Aggarwal and Samwick 1999a). However, these additional controls (i.e., those not included in BLN) do not significantly affect the implications of our methodological changes.

[13] The Herfindahl is calculated using all Compustat firms and for each of the Fama-French 48 industry groups.

We propose two methodological changes relative to BLN. The first is relatively innocuous and consists of considering log compensation rather than compensation. While results are largely similar across these specifications, results using log compensation are less sensitive to outliers and small sample problems, and the skewness of the regression residual errors is no longer rejected as consistent with the normal distribution in the case of using compensation (results available upon request).

The second methodological change we propose is more critical. Specification (1) assumes that, after controlling for the performance, tenure, and economy-wide variables, changes in compensation follow a random walk. However, this ignores the very significant positive autocorrelation of firms' CEO compensation across time. For example, a pooled panel regression of log CEO compensation on a constant and its one-year lag gives an R^2 of 56% and an AR(1) coefficient of 0.76, which is quite significantly smaller than 1. Because of this, the first difference of (log) compensation has very significantly *negative* autocorrelation. For negatively autocorrelated variables, a relatively low (high) value tends to be followed by a subsequent increase (decrease). Therefore, without adjusting changes in (log) compensation for strong negative autocorrelation, there is, by construction, a large positive association between changes in compensation and both CEO compensation benchmarking proxies described above. In particular, negatively autocorrelated changes in (log) compensation mean that firms with previous compensation decreases tend to increase their compensation the subsequent year. However, firms with previous compensation decreases are also more likely to have low compensation relative to their benchmark, such that this negative autocorrelation, if not corrected for, could significantly increase evidence for benchmarking.

Fortunately, such effects are relatively easy to correct for by controlling for the lagged level of CEO compensation. Note that controlling for the lagged level of CEO compensation should not affect the evidence for benchmarking in a well-specified regression. Benchmarking specifically links

the change in CEO compensation to its distance to the compensation of *other* firms, not its distance to its *own* lagged compensation.

Table 7 shows the importance of controlling for the lagged level of CEO compensation in the benchmarking regressions similar to those run in BLN, using changes in log CEO compensation as the dependent variable and the Low Compensation Dummy (in Panel A) and CDF Distance (in Panel B) as the benchmarking proxies. In the first two columns of each panel, the specifications do not control for lagged compensation. The lagged compensation is then added in the last two columns. Throughout the paper, robust standard errors clustered by firm are used and only include CEOs with at least 2 years of tenure to make sure that all compensation changes are for the same CEO.

In Panel A, the coefficient on the Low Compensation Dummy equals 0.458 and is highly significant in column 1, and is hardly affected by adding industry dummies in column 2. However, controlling for lagged compensation in column 3 lowers the coefficient on the benchmarking dummy to 0.017, which is insignificant (p-value of 30%). Once industry dummies are added in column 4, the coefficient on the Low Compensation Dummy equals -0.006 (thus with the opposite sign) and is insignificant. In contrast, the lagged compensation variable is highly significant and its addition almost doubles the R^2. The results in Panel B using CDF Distance as the proxy for benchmarking likewise show a very strong reduction in the evidence for benchmarking once lagged compensation is controlled for: the coefficient on CDF Distance drops by about 90%, from 1.010 (column 2) to 0.0093 (column 4), where it is only statistically significant at the 5% level.

Without taking logs, the results are even stronger (results unreported but available upon request). For example, the coefficient on the Low Compensation Dummy equals $1,743 without controlling for lagged compensation (similar to the results in BLN), but changes to -$342 with the control, i.e., with the opposite sign. The same sign reversal happens for the CDF Distance as the proxy for benchmarking.

Overall, once lagged compensation is controlled for, we find much weaker or no evidence for benchmarking. In the next subsection, we will explore whether there is more evidence for benchmarking across different industries depending on each industry's CEO talent pool structure.

3.2 Benchmarking and CEO Talent Pool Structure

Our main goal is to explore how important are peer groups in determining CEO compensation. We previously documented that CEO talent comes from pools that are clearly distinct by industry, with significant differences in the number of insiders across industries. To form the analysis in this section, we divide industries into quartile groups based on their CEO talent pool structure. First, we divide industries into quartile groups based on the percentage of new CEOs across the whole sample who are insiders.[14] The dummy indicating firms in the 25% of industries where CEO talent pools are mostly firm-specific, i.e., where the large majority of CEO candidates come from inside the firm, is denoted as the "high-insider" (percentage) group dummy, and the dummy for firms in the bottom quartile of insider CEOs is the "low-insider" group dummy.

Second, we divide industries into quartile groups based on the percentage of new *outsider CEO*s who come from firms in the same industry. The dummy for firms in the 25% of industries where the CEO talent pool is most industry-specific is denoted as the "high-outsider-industry" group dummy, and the dummy for firms in the 25% of industries with the fewest new outsider CEOs from within the industry is the "low-outsider-industry" group dummy.[15] The high-insider and the low-outsider-industry dummies are naturally correlated (35%), and likewise the low-insider and the high-outsider-industry dummies (32%).

[14] We use the whole sample to reduce noise and because there is almost no time variation in the percentage of insiders across industries.

[15] We again use the Fama-French 48 industries, and use CEO replacements from the whole sample. Dividing the time-series into three sub-periods and calculating the percentage of insiders and of outsiders-from-the-same-industry gives similar results. Also, because we create industry quartile groups, the number of firm-years in each group is slightly different from 25%, but all four groups have between 23% and 25% of firms.

One would expect the CEO compensation of firms in the "low-insider" and the "high-outsider-industry" group to be most affected by benchmarking against other firms with a similar size in their industry. For these groups, there are significant outside opportunities for the CEOs, while those firms also have to remain competitive in their ability to attract top talent from other firms. Once both are incorporated simultaneously, one would expect the high/low-insider dummies to become first-order effects, while the high/low-outsider-industry dummies would capture the importance of having outsiders from within the industry or from outside the industry.

We interact the two benchmark proxies with the four CEO talent pool structure dummies, and present the results in Table 8. Panel A shows the regressions using the Low Compensation Dummy as our proxy for benchmarking. The first column shows the unconditional benchmarking results as in Panel B of Table 7 with some additional controls and industry dummies. The first added controls are a dummy indicating whether the CEO is an outsider, the percentage of insiders and the percentage of outside CEOs from the same industry, which are later used to interact with the benchmarking dummies. In the next two columns, we interact the benchmarking proxy with the "high/low insider" and the "high/low-outsider-industry" dummies, without and with industry fixed effects in the second and third column, respectively.

In column 1 of Panel A, the coefficient of the Low Compensation Dummy by itself (i.e., without interaction) is insignificant, as before. While Murphy and Zabojnik (2007) find that outside CEO are paid more (in levels), the compensation changes of outside CEOs are higher, but the effect is not significant.[16] We also find a marginally significant industry-wide effect that a lower percentage of insiders in the industry is associated with greater increases in compensation. Further, CEO compensation changes in concentrated industries are higher.

Column 2 shows that there is still significant evidence for benchmarking in industries with many outsiders. The Low Compensation Dummy is significantly positive and relatively large

[16] The p-value of the Outside CEO Dummy is about 12%. The coefficient of the Outside CEO Dummy is positive and significant at the 5% level if one does not control for stock market volatility.

(coefficient of 0.102) when interacted with the Low Insider Dummy. In contrast, its interaction with the High Insider Dummy is not significant, nor is the proxy by itself (i.e., without interaction) significant. Further, it is only the percentage of insiders in the industry that seems to matter for benchmarking, not whether any such outsiders come primarily from the same industry. Finally, column 3 indicates that these results are robust to adding the industry fixed effects. Therefore, there is no evidence for benchmarking in industries where the CEO is coming mostly from within the firm, but when a large percentage of CEOs in the industry are from outside the firm, benchmarking seems an important part of compensation dynamics. In fact, because the unconditional effect is not significant, evidence for benchmarking exists *exclusively* in industries with many outsider CEOs.

Panel B has the analogous results using the CDF Distance measure as our proxy for benchmarking. The results are quite similar to those in panel A: once industry fixed effects are included, benchmarking is only significant for firms in industries with many outsider CEOs. Adding the Outside CEO Dummy to the specification with industry fixed effects (column 1) makes the coefficient on the CDF Distance by itself insignificant, such that there is no longer unconditional evidence for benchmarking. Further, the differences in benchmarking between industries with many and few outside CEOs in column 3 are particularly large, namely 19% more and 13% less likely than on average, respectively.

Our results contribute to the findings of BLN in two ways. First, controlling for lagged essentially takes away the average effect of benchmarking on the dynamics of executive compensation. Second, in the subset of firms in industries with high percentage of outsider CEOs, there is still very strong evidence for benchmarking. Because the unconditional effect is not significant, evidence for benchmarking exists *exclusively* in industries with many outsider CEOs, which is consistent with competitive benchmarking and CEO labor market considerations.[17]

[17] Our results also do not change if we add the proxy for the general level of outside opportunities for all top executives (including the CEO) in other industries, or interact that proxy with benchmarking (interactions are insignificant, though interactions with the percentage of outside CEOs in the industry remain significant).

4. Pay-for-Luck

CEO compensation may change not only with firm-specific performance, but also with the industry or even economy-wide performance. This finding stands in seeming contrast to the intuition of e.g. Holmstrom (1979) that CEOs should only be paid for the part of performance that they can influence (denoted by "Skill"), and not for the performance that is due to other factors such as industry-wide shocks (denoted by "Luck").[18] Bertrand and Mullainathan (2001) argue that 'pay for luck' is a manifestation of an agency conflict. In contrast, Himmelberg and Hubbard (2000) and Hubbard (2005) argue that pay for luck can be due to the correlation between the value of CEO skill and market conditions. When the industry is booming, the value of CEO skill increases and therefore the CEO should receive higher compensation.

In this section, we explore the relation between pay for luck and the structure of CEO talent pools. To the extent that pay for luck is the result of changes in the value of CEO skills, shocks within pools, rather than outside pools, should explain CEO compensation. Specifically, in an industry with many outsider CEOs and where the overall supply of CEOs will be relatively inelastic, boards may be forced to raise their CEOs compensation if there is a positive industry-wide shock. An industry-wide boom clearly improves each CEO's next best alternative in those industries. However, in industries with very few outsider CEOs, such a competitive labor market argument would be less compelling, if CEOs and top executives are beholden to the firm and (almost) never move to outside opportunities.

4.1 Methodology for Measuring Pay-for-Luck

Our measure of performance is the firms' annual excess stock return (dividends reinvested, above the risk-free rate). This measure has a large explanatory power for cross-sectional variations in CEO compensation (Jensen and Murphy 1990), and is commonly used. To separate the

[18] DeMarzo et al. (2009) show in a dynamic agency problem that luck could optimally enter compensation contracts.

component of performance that is due to luck from the component that is due to skills, our two-stage regression closely follows Garvey and Milbourn (2006) and BLN. In the first stage, we conduct a pooled panel regression of annual firm excess stock returns on value- and equally-weighted industry excess stock returns, industry dummies and year dummies, using the 48 Fama-French industry groups.[19] Next, the estimated coefficients are used to calculate the component of the return that is explained by the industry returns and the industry and year dummies. As in Garvey and Milbourn (2006) and BLN, we define this fitted component as the "luck" component of the return, which is not explained by the firm-specific CEO skills. The regression residual, i.e., the difference between the annual return and the luck component, is denoted as the "skill" component. We then scale these two components of the return by the log of the market capitalization of the firm in the beginning of the year. We define these two components as Skill and Luck.

In the second stage, we regress changes in log compensation on Skill and Luck plus controls, year dummies and firm fixed effects. We further interact the proxies of Skill and Luck with the high/low-insider, and the high/low-outsider-industry dummies. The controls are similar to those used in the benchmarking test.

4.2. Results

The results of the second stage are given in Table 9. The first column includes Skill, Luck the cumulative distribution function of CEO volatility, plus the other control variables from Table 5 including lagged CEO compensation. Both Skill and Luck have statistically significant and economically large effects on CEO compensation. Using column 2, a 1% increase in the Skill component of stock market performance is associated with a 0.243% increase in compensation, and a 1% increase in the Luck component is associated with an about 0.165% increase in compensation.

[19] We use both equal-weighted industry returns and value-weighted industry returns in the regression to ensure that our results are not biased because of the size distribution within industries. We tried both French's 48 industry classification of industries and the 10 industry classification in the first stage, and results using either are very similar.

Next, we consider the effect of CEO talent pool structure. In column 2, we interact Skill and Luck with dummies for whether the industry has a high and low percentage of inside CEOs. We find that Skill remains significantly different from zero, but there is no significant difference in the elasticity of compensation changes to the firm-specific component of performance (i.e., Skill) across industries with high and low percentages of insiders. In contrast, while Luck by itself remains significant, Luck or the industry-wide performance component is statistically significantly (p-value of 7%) larger in industries that have a low percentage of insider CEOs, while Luck interacted with the "high-insider" dummy is insignificant. Economically, the coefficient on Luck is almost twice as large for firms in industries with many outsiders compared to the average. This result is consistent with the argument that pay-for-luck is at least partly driven by outside opportunities to the CEO. When the pool for CEOs is largely other executives within the firm, CEO compensation responds less Luck or the industry-wide performance component of compensation.

Column 3 shows variation in the relation between Skill and Luck across industries with high and low levels of CEOs from the same industry. We do not find a variation in the two components across this classification of industries. Our interpretation for this result is that what matters is whether the CEO skill is firm-specific. Whether CEOs are coming from the same industry or from other industries still leaves them with outside opportunities that are affected by industry shocks. Finally, in column 4 we add the interactions of Skill and Luck with both high/low levels of insider CEOs and high/low levels of outsider CEOs from the same industry, and find that the results from column 2 are robust. What we find to matter is only the levels of outsider CEOs, not whether these come from other industries. These results are also consistent with the benchmarking results in section 3.

5. Talent Pools, Firm Size, and CEO Skill

Gabaix and Landier (GL) analyze the relation between managerial talent and CEO compensation. In their general-equilibrium setting, all firms choose managers from the same pool of talent. Following the insight of Rosen (1992) that productivity of talent increases with firm size, their matching model implies a relation between CEO compensation and the size distribution across large public companies. Empirically, their results rely on the assumption of firm size proxying for CEO talent.

Under some mild distributional assumptions of firm size in the economy, GL show that the compensation to the CEO should be related both to the size of the firm in which the CEO operates and the size of the n^{th} largest firm in the economy, where n is a constant. They then test this prediction using the following specification on a panel of large public US firms:

$$Log\ (CEO\ compensation_{it}) = a_0 + a_1\ Log(Size_{it}) + a_2\ Log(Size_Reference_Market_t) + e_{it}$$

The variable $Size_Reference_Market_t$ is the size of the m^{th} largest firm in the economy. Theoretically, m could be any size ranking as long as it captures the tail of the size distribution. In their empirical specification, GL use m=250 (the 250^{th} largest firm is the reference firm). GL acknowledge that if talent pools are segmented, then "…the reference firm size should be industry-specific which will lead to an attenuation bias in the coefficient on the reference firm size" (GL page 35).

In this section, we wish to explore the extent to which firm-specific and industry-specific variations in CEO talent pools help explain variations in the compensation. Previously, we documented large differences in CEO talent pools across industries. In pools of CEO candidates that are highly segmented, the GL model would predict that what matters is not the size distribution of firms in the whole economy, but the size distribution of firms within the particular talent pool.

To test the effect of the industry specific talent, we first run the following regression over the entire Execucomp data between the years 1993-2005:

$$Log\ (CEO\ compensation_{it}) = a_0 + a_1\ Log(Size_{it}) + a_2\ Log(Size_Reference_Market_t) + a_3\ Log(Size_Reference_Industry_t) + e_{it}$$

This specification is similar to GL, except that we add another reference firm which is industry specific. $Size_Reference_Industry_t$ is the size of the 20th largest firm in Compustat that belongs to the same industry as the CEO's firm (using the 48 industry specification of Fama and French (1997)). We define firm size as the market value of the equity of the firm (as this gives clearly higher R^2 than using total cap that includes the book value of debt, as used in GL, though results are very similar when using total cap). Finally, we adjust compensation and market capitalizations for inflation (as we cannot use year fixed effects).

5.1 Market and Industry Reference Firm Size

Table 10 shows the results. Column 1 shows the results of the GL specification. As expected, the coefficients of both market size and the size cohort are significant. Column 2 shows the GL results once we introduce industry-specific reference firms. For each of the 48 industries we find the size of the largest 20th firm (using all firms in the Compustat database, not just those firms in the ExecuComp sample). The size of the largest 20th firm is used as an additional explanatory variable to help explain variation in compensation over time. The results show that variations in the size of the industry-reference firms do not explain any variation in the CEO compensation. The coefficient is not statistically different than zero. In contrast, the market reference firm is still statistically significant from zero.

One interpretation of these findings is that the markets for CEO talent are integrated and therefore the change in the size distribution of firms across the entire economy is the relevant indicator for the change in the return to talent in our sample. However, this result seems inconsistent with our documentation that the labor market for CEO is relatively fragmented. To further explore the result we check whether the effect of the market reference firm or the industry reference firm will differ between industries with high percentage of CEO insiders and industries with high percentage of CEO insiders. We expect firms in industries with a high percentage of CEO insiders to be affected less by reference size variables because, to the extent that these reference size variables represent distribution of skill in top firms, these should be less relevant when the market for talent is firms specific.

We repeat the strategy in the previous sections, and interact each of the variables in equation 4 with whether the firm belongs to industry with high percentage of insider CEOs (top quartile) or to industry with low percentage of insider CEOs (bottom quartile). We also add the percentage of insiders in the industry as a control variable to capture any effect of insiders on compensation levels, not captured by the interaction terms.

Column 3 shows that, overall, there is a small effect of the CEO talent pool on the coefficients of firm size, and the size of the reference firms both in the economy and in the industry. However, we find very limited support for the hypothesis that the importance of the industry and market reference firm sizes should depend on the CEO talent pool structure. Firms that belong to industries with a high percentage of insiders are slightly less affected by variations in economy-wide reference firm size than firms with low-percentage of insiders, but the coefficient and thus the economic significant of the effect is quite small. Further, the effect of the industry reference firm goes in the opposite direction, where we find a slight positive relation between the percentage of insider CEOs in the industry and industry reference firm size, as the coefficient of the interaction

between industry reference firm and the high-insider dummy is significantly larger than the coefficient of the interaction between industry reference firm and the low-insider dummy.

We suggest several explanations for this finding. First, it may be the case that executive talent makes career decisions early on, knowing that once they enter certain industry they close off other options outside that industry. In that case, more talented potential CEOs may enter industries where they expect higher rewards, and vice versa for less talented potential future CEOs. This could generate equilibrium compensation that is again driven by market-wide, not industry-specific factors, even if CEO talent is not homogeneous across industries at the CEO stage of talent's careers.[20]

Empirically however, we find that insider CEOs typically have very long tenures with their own firm before becoming CEOs. For example, more than 90% of new insider CEOs have been with their firms 5 years or more. It seems likely that many of those CEOs made their career decisions many years before that. As a result, projections regarding the potential growth of different industries would arguably seem to be hard to make that far in advance by young executive talent deciding on their career path.

Second, the size of the market-wide reference firm may proxy for something else not directly related to the equilibrium model in GL. Recent papers challenging the interpretation of GL include Frydman and Saks (2007), who find a much smaller elasticity between CEO compensation and average firm size with data starting in 1936, as well as Dew-Becker and Gordon (2007), who find widely varying elasticities for 1970-2005 compensation data using rolling 20-year regressions.

6. Conclusion

Our results suggest that there are two important and different markets for CEO talent. The first market is external and is composed of managers and CEOs from other companies (largely

[20] We thank Xavier Gabaix for proposing and illustrating this possibility in his NBER discussion of our paper.

within the same industry). The second is the internal market for CEOs. Compensation to CEOs whose market is internal does not respond to industry shocks and is less strongly tied to industry performance. Compensation to CEOs whose market is external responds to industry shocks and is tied to industry performance.

These findings stand in contrast to the widely held belief that CEO skills are homogenous. They further suggest that the forces which determine executive compensation could be both driven by outside market pressure and by internal bargaining and that the importance of each force differs depending on the talent pool structure within the firm.

In this paper we studied the effect of talent pool structure on executive compensation. We believe that talent pool structure has important implications not only on CEO compensation but also on other firm policies such as CEO replacements and board structure decisions. We plan to explore these issues in future research.

Finally, our results question the use of firm size as a proxy for the relative talent of different CEOs (Rosen 1992) and the interpretation of the empirical results in Gabaix and Landier (2008). Their model and specification assume homogeneity in CEO skills across firms, while their empirical results reply on the assumption that firm size can proxy for CEO talent. Having documented the importance of heterogeneous firm- and industry-specific skills, we find that variations in firm size (used as a proxy for talent in GL) within industries explain only a very small portion of the variation in CEO compensation over time.

TABLE 1: DATA CONSTRUCTION

The table shows the construction of the database of new CEOs. The sample consists of all CEOs in the Execucomp database between 1993 and 2005. From that sample, a subsample of new CEOs was extracted. The final sample of new CEOs consists of 1,827 persons.

Total number of Execucomp firm years (93-05):	24,084
Firm years with unidentifiable CEOs	2,745
Total number of firm years with CEOANN	21,339
Identifying additional CEOs:	2,064
Total firms with CEO info:	23,403
Number of firm-years with new CEOs:	1,890
No proxy information about the past experience of the CEO	63
Total number of firm years with New CEOs that have available data	1,827

TABLE 2: CHARACTERISTICS OF NEW CEOS

The table shows the characteristics of new CEOs in the Execucomp database. Panel A shows the distribution of new CEOs by Insiders, Outsiders, and Interim. Insider CEOs are CEOs whose previous position in the previous two years was with the same company. Interim CEOs are new CEOs who were replaced within a year from becoming CEOs, or who declared in the proxy statement that they are interim CEOs once they took their position. In panels B, C, and D, the information about previous employment of the CEOs is from the proxy statements, which provides information about the employment history of the CEO within the past five years. If the CEO's past employment was for less than 6 months, we take the previous employment record.

Panel A: Insiders, Outsiders, and Interim CEOs

Period	All CEOs	Insiders	Outsiders	Interim
1993-1996	498	312	152	34
		63%	31%	7%
1997-1999	463	284	146	33
		61%	32%	7%
2000-2002	466	313	122	31
		67%	26%	7%
2003-2005	400	238	127	35
		60%	32%	9%
1993-2005	1,827	1,147	547	133
		63%	30%	7%

Panel B: Former Employment of Outsider CEOs

Period	Total Outsiders	Former CEOs	Former CEOs from Public Firms	Former CEOs from private Firms	Former Non CEOs	Former Non CEOs from Public Firms	Former Non CEOs from Private Firms
1993-1996	152	47	28	19	105	71	34
		31%	18%	13%	69%	47%	22%
1997-1999	146	44	25	19	102	72	30
		30%	17%	13%	70%	49%	21%
2000-2002	122	36	30	6	86	59	27
		30%	25%	5%	70%	48%	22%
2003-2005	127	46	23	23	81	59	22
		36%	18%	18%	64%	46%	17%
1993-2005	547	173	106	67	374	261	113
		32%	19%	12%	68%	48%	21%

Panel C: Former Employment of Outsider CEOs with No Prior CEO Experience

Lower ranked Manager (of a division / subsidiary/VP)	213	43%
COO	40	8%
President	56	11%
CFO	9	2%
Director	18	4%
Investor	4	1%
	340	

Panel D: Former Employment of Insider CEOs

(Note: the sample consists of 599 CEOs, which is about 52% of all insider CEOs)

	Entire period	93-96	97-99	00-02	03-05
Chief Operating Officer	39%	38%	36%	40%	44%
Manager of a division / Vice President	23%	21%	29%	22%	17%
President	20%	29%	19%	17%	14%
CEO of a subsidiary / acquired company	9%	7%	8%	11%	10%
CFO	4%	1%	4%	4%	9%
Owner/Founder	3%	2%	3%	4%	3%
Director	2%	1%	2%	2%	3%
Former CEO of company	1%	3%	0%	1%	1%

TABLE 3: INDUSTRY DISTRIBUTION OF OUTSIDER CEOS

The table shows the distribution of new CEOs across industries from the sample of all new CEOs between 1993 and 2005, and whose firm is in Execucomp, using 10 (Panel A) and 48 industry groups (Panel C). For the outsider CEOs and 10 industry groups, Panel A also shows the number (and as a percentage in two ways: first as the percentage of all CEO coming to that industry, secondly as the percentage of all CEO from that industry) of outsider CEOs who came from a given industry and ended up as CEOs in a different industry. Panel B shows the meaning of the industry abbreviations which are used in Panel A.

Panel A: Transition Matrix of new CEOs

TABLE 4: EXPLAINING INDUSTRY TALENT POOL STRUCTURE

The table shows regression results where the data is at the Fama French 48 industry level. The dependent variable is the percentage of replacements within the industry in which the new CEO's former employment was inside the firm (columns 1-2) and outside the firm's industry (columns 3-4). The data in calculated every year,. The Herfindahl Concentration measure is calculated using the sales of all firms in the industry in Compustat. CapEx/Sales is the ratio of capital expenditures over sales. R&D/Sales is the ratio of research and development expenditures over sales. Q is the market value of equity plus book value of liabilities, divided by book value of assets. Growth is the change in log of aggregate industry sales from the previous year. The CEO replacement Rate is the number of replaced CEOs at the industry level divided by total number of firms in the same industry in Execucomp. Errors are clustered at the industry level. *, **, *** are significance at the 10%, 5%, and 1% level respectively.

Dependent variable:	**Percent of Replacements from Inside the Firm, by Industry**						**Percent of Replacements from Outside the Industry, by Industry**

TABLE 5: CEO COMPENSATION - DESCRIPTIVE STATISTICS

The table presents descriptive statistics of the variables used in the analysis: sample average ('Mean'), standard deviation ('St.Dev.'), minimum ('Min.') and maximum ('Max.'). $TDC1_t$ is the total CEO compensation in year t and is taken from Execucomp. The 48 industry groups are from the Fama-French classification. The Herfindahl concentration measure is based on sales of all firms in Compustat. Volatility, Beta and the change in log Sales are from ExecuComp. ROE is net income over book value of equity from Compustat. MarketCap is the equity market capitalization. MarketCap_250 is the equity market capitalization of the 250th largest firm in Compustat. Tenure is the number of years since the CEO took place. Percentage of Equity-Based Compensation measures the flow of incentives, i.e., the ratio of the value of restricted stock grants and option grants over total compensation (TDC1). Stock Incentives is the stock of equity-based incentives, i.e., the sum of the value of restricted stock holdings and option grants (exercisable and unexercisable), from ExecuComp.

	Mean	St.Dev.	Min.	Max.
$Log(TDC1_t)$	8.055	1.013	5.504	10.570
Outside CEO dummy	0.170	0.376	0.000	1.000
Percentage of Inside CEOs, in 48 Industry Group	0.732	0.100	0.553	0.909
Percentage of Outside CEOs from outside the industry, in 48 Industry Group	0.121	0.053	0.000	0.209
Outside CEOs from top executives / # of firms, in 48 Industry Group	0.005	0.003	0.001	0.010

Log(Stock Incentives)	8.211	1.914	0.000	16.650

TABLE 6: CEO COMPENSATION AND TALENT POOL STRUCTURE: LEVEL, GROWTH AND COMPOSITION

The table shows regression results of the relation between CEO compensation and talent pool structure. The dependent variables are log of total compensation (TDC1), the log growth of total compensation, the percentage of equity-based compensation and the log of equity-based CEO holdings, respectively, on four proxies related to CEO talent pools and controls. TDC1 is the total CEO compensation and is taken from Execucomp. The sample for log growth of compensation is smaller as we only consider CEOs with tenure of at least 2 years. Percentage of Equity-Based Compensation is the ratio of the value of restricted stock grants and option grants during the year over total compensation (TDC1). Equity-based Holdings is the sum of the value of restricted stock holdings and option holdings (exercisable and unexercisable) at the end of the year. For a description of the controls, see Table 5. The numbers in parentheses are robust standard errors clustered at the firm level. ***, **,* represent significance at the 1%, 5%, and 10% levels, respectively.

	$Log(tdc1_{t-1})$			$Log(tdc1_{it})$-$Log(tdc1_{it-1})$			Percentage of Equity-Based Compensation			Log(Equity-based Holdings)

TABLE 7: BENCHMARKING

The table shows regression results of changes in log compensation on two benchmarking proxies and controls. In panel A, the benchmark proxy is a dummy variable for whether the CEO compensation last year was lower than the median compensation of its 48-industry-2-size group in the previous year. In panel B, the benchmark proxy is the cumulative distribution function of the median compensation of its industry-size group minus the CEO compensation during the previous year (CDF Distance). TDC1 is the total CEO compensation and is taken from Execucomp. Market Cap_250 is the equity market capitalization of the 250th largest firm in Compustat. Tenure is the number of years since the CEO took place. The numbers in parentheses are robust standard errors clustered at the firm level. ***, **,* represent significance at the 1%, 5%, and 10% levels respectively.

TABLE 8: BENCHMARKING AND TALENT POOLS

The table shows regression results of changes in log compensation on two benchmarking proxies interacted with CEO talent pool structure and controls. In panel A, the benchmark is a dummy variable for whether the CEO compensation in the current year is lower than the median compensation of its industry-size group in the previous year. Industry grouping is according to Kenneth French's 48 industry classification. Within each industry and each year, we further classify firms into large and small–size based on whether they are above or below the median equity market capitalization for all Compustat firms within the industry in the particular year. In panel B, the benchmark proxy is the cumulative distribution function of the median compensation of its industry-size group minus the CEO compensation during the previous year (CDF Distance). Low (High) Insider is a dummy variable for whether the industry to which the firm belongs is at the bottom (top) 25% in terms of the percentage of CEOs that are coming from within the firm. Low (High) Outsider Industry is a dummy variable for whether the industry to which the firm belongs is at the bottom (top) 25% in terms of the percentage of outsider CEOs that are coming from within the same industry. The rest of the variables are defined in Table 4. The numbers in parentheses are robust standard errors clustered at the firm level. ***, **,* represent significance at the 1%, 5%, and 10% levels respectively.

TABLE 9: PAY FOR LUCK

The table shows the regression results where the dependent variable is the change in Log compensation between the current year and the previous year, including year and firm fixed effects. The variable Luck is the fitted return from a pooled regression of annual firm returns on value- and equally-weighted industry returns plus year and industry fixed effects (using 48 industry groups). The variable Skill is the difference between the annual firm return and Luck. Low insider is a dummy variable for whether the industry to which the firm belongs is at the bottom 25% in terms of the percentage of CEOs that are coming from within their own firm. High insider is a dummy variable for whether the industry to which the firm belongs is at the top 25% in terms of the percentage of CEOs that are coming from within the firm. Similarly, Low (High) Outsider Industry is a dummy variable for whether the industry to which the firm belongs is at the bottom (top) 25% in terms of the percentage of outsider CEOs that are coming from within the same industry. CDF BS Volat is the cumulative distribution of the stock return volatility of the firm relative to all firms in Execucomp, where the volatility is from Execucomp. The rest of the variables are defined in Table 5. The numbers in parentheses are robust standard errors clustered at the firm level. ***, **,* represent significance at the 1%, 5%, and 10% levels respectively.

TABLE 10: GABAIX AND LANDIER RESULTS (2008) AND TALENT POOLS

The table shows the results of panel regressions where the dependent variable is the natural log of CEO compensation. The sample consists of all Execucomp firms with CEO compensation information between the years 1993-2005. CEO compensation is the variable tdc1 from Execucomp and it consists of the sum of salary, bonus, value of restricted stock, and Black-Scholes value of option grants for the fiscal year. The independent variable log (Total cap) is the natural log of the market capitalization of the firm at the end of the fiscal year. Market Cap Ref. $Firm_t$ is the equity market capitalization of the 250^{th} largest firm in the Compustat database. Both compensation and market caps are inflation-adjusted. Low insider is a dummy variable for whether the industry to which the firm belongs is at the bottom 25% in terms of the percentage of CEOs that are coming from within their own firm. High insider is a dummy variable for whether the industry to which the firm belongs is at the top 25% in terms of the percentage of CEOs that are coming from within the firm. The industry classification is based on the 48 industries in Fama and French (1997). The numbers in parentheses are the standard deviations of the coefficients. All errors are clustered at the firm level. *** indicates significance at the 1% level.
